## Radionuclide Information Booklet

The purpose of the *Radionuclide Information Booklet* is to provide practical information to aid radiation protection specialists at Canadian Nuclear Safety Commission (CNSC) licensed facilities.

The *Radionuclide Information Booklet* contains information pages for radionuclides commonly used in the medical, research, and industrial sectors. These information pages may be posted at CNSC-licensed facilities as a convenient way to quickly find information.

The information pages within the *Radionuclide Information Booklet* are organized by atomic number (Z). However, it is important to ensure the most recent information pages are being used, and it is ultimately the user's responsibility to use the information appropriately. The following sections describe each of the six parts of the *Radionuclide Information Booklet* pages.

It is important to also consult your CNSC licence, the *Nuclear Substances and Radiation Devices Regulations*, and the *Radiation Protection Regulations* for CNSC's regulatory requirements as the *Radionuclide Information Booklet* does not replace them.

### Part 1 – Radionuclide identification

This section includes the chemical symbol, common name, atomic weight, and atomic number of the specified radionuclide.

### Part 2 – Radiation characteristics

This section includes the physical half-life and decay scheme. The source of this information is the Joint Evaluated Fission and Fusion (JEFF) 3.1 nuclide library, accessed through the Nucleonica Nuclear Science Portal, using the Datasheets application [1]. The decay scheme shows both the half-life and decay mode for each step in the decay chain. The following nomenclature is used: “s” for seconds, “m” for minutes, “d” for days, “y” for years, “ $\alpha$ ” for alpha, “ $\beta(-)$ ” for beta, “ $\beta(+)$ ” for positron, “EC” for electron capture, and “IT” for isomeric transition.

The energies of the three most abundant emissions and the energies of the three most energetic emissions are provided with their emission probabilities in brackets. When radioactive progeny are in equilibrium with the nuclide of interest, the emissions from the radioactive decay products are also considered. The source for this information is the JEFF 3.1 nuclide library and the 8th Table of Isotopes, accessed through the Nucleonica Nuclear Science Portal [1]. Only energies above 10 kiloelectron volts (keV) and/or emission probabilities greater than 0.01% were included, with the exception of Fe-55, which has no emissions with energies above 10 keV. The energies provided for electron, beta, and positron radiation are the maximum end-point energies.

Also included are:

- (1) First and second half value layers (HVL) and tenth value layers (TVL) for shielding photons using lead, steel and concrete. These broad beam HVL and TVL values were obtained using Nucleonica's Dosimetry & Shielding application [2]. The application uses NIST mass attenuation coefficient tables [3] in conjunction with build-up factors from ANSI/ANS-6.4.3-1991. In the case of concrete, Nucleonica uses ordinary concrete (2.3 g/cm<sup>3</sup>) from NIST's mass attenuation coefficient table for mixtures and compounds [4]. The application defaults to a low energy cut-off value of 15 keV. For validation, select TVL values were also compared against other references (see appendix A).

Below are three scenarios which provide different equations for calculating attenuated dose rate using HVLs and TVLs.

**Scenario 1:** If the thickness of shielding is less than one first HVL, the dose rate can be estimated using the equation below:

$$R = (\Gamma \times A \times 2^{-t/HVL1}) / d^2$$

**Scenario 2:** If the thickness of shielding is more than one first HVL but less than one first TVL, the dose rate can be estimated using the equation below:

$$R = (\Gamma \times A \times 0.5 \times 2^{-[t-HVL1]/HVL2}) / d^2$$

**Scenario 3:** If the thickness of shielding is greater than one first TVL, the dose rate can be estimated using the equation below:

$$R = (\Gamma \times A \times 0.1 \times 10^{-[t-TVL1]/TVL2}) / d^2$$

<b>Where:</b>		
R	is the dose rate	( $\mu$ Sv/h)
$\Gamma$	is the gamma ray constant for the source at 1 m	( $\mu$ Sv/h per GBq)
A	is the activity of nuclear substance	(GBq)
d	is the distance between the nuclear substance and the location	(m)
t	is the thickness of shielding material, in the direction of travel,* in any shielding wall between the nuclear substance and the location	(mm)
HVL1	is the thickness of shielding material to reduce the unshielded dose rate to one half of the original	(mm)
HVL2	is the thickness of shielding material, in addition to the first HVL, to reduce the dose rate by another half	(mm)
TVL1	is the thickness of shielding material to reduce the unshielded dose rate to one tenth of the original	(mm)
TVL2	is the thickness of shielding material, in addition to the first TVL, to reduce the dose rate by another one tenth	(mm)

Note: If the radiation is penetrating a shielding wall at an oblique angle, the actual thickness of the shielding will be greater than the thickness of the wall.

To calculate the attenuated dose rate using Microsoft Excel, the following syntax can be used (where “X” is the shielding thickness and “DR” is the unshielded dose rate): =DR\*IF(X>=TVL1, 0.1\*10<sup>^</sup>(-(X-TV L1)/TVL2), IF(X>=HVL1, 0.5\*2<sup>^</sup>(-(X-HVL1)/HVL2), IF(X<HVL1, 2<sup>^</sup>(-(X/HVL1))))).

- (2) The continuous slowing down approximation (CSDA) ranges in mm, are provided for aluminum, Polymethyl methacrylate (PMMA, a.k.a. Plexiglass), water (liquid) and air (dry, sea level) for electrons and/or positrons. These were obtained using Nucleonica’s Range & Stopping Power application [5]. The application is not nuclide specific but requires the user to enter the end point electron (or positron) energy. The most energetic emission from each nuclide’s table, with a probability above 1%, was used. For example, Se-75’s 3 most abundant electron emissions are at 12.51 keV (4.4%), 84.9 keV (2.6%), and 124.1 keV (1.6%). In this case, the 124.1 keV electron emission was chosen for the CDSA ranges.

When energetic electrons and beta radiation interact in high Z material (e.g., lead), electromagnetic radiation called bremsstrahlung is produced. Therefore, high Z materials such as lead may not be appropriate shielding materials for energetic electrons and beta radiation and low Z material should be used first. For low-energy electron or beta emitters such as tritium and carbon-14, bremsstrahlung production is not significant.

## Part 3 – Dose rate constants and coefficients

### External dose

In this section, dose coefficients are provided for estimating skin dose from direct contamination and whole body effective dose from external exposure to radiation sources. The gamma ray effective dose rate at one meter assumes a point source and anterior-posterior geometry. These values were calculated based on the International Commission on Radiological Protection's (ICRP) fluence-to-effective dose conversion coefficients (linearly interpolated when necessary) provided in ICRP Publication 116 [10] and the photon energies and probabilities obtained from the JEFF 3.1 or 8th Table of Isotopes nuclide library [1]. All photon emissions above 15 keV with a probability above 0.01% were considered in the calculation. The 15-keV low energy cut-off was chosen to match the default cut-off value applied in the Nucleonica application used to calculate HVLs and TVLs, but also to reflect the fact that photons at energies between 10 keV and 15 keV are significantly attenuated by the source container (e.g., steel, plastic, glass vial, human patient, etc). To be conservative, attenuation and build-up in air was not incorporated in the calculation.

The dose rate from skin contamination was calculated using Varskin 5.3 [6]. Each nuclide's skin dose coefficient (including radioactive decay products when applicable) was calculated using a 1 cm<sup>2</sup>, 1000-Bq disk source directly on the skin (i.e., no air gap, no cover thickness), averaged over 1 cm<sup>2</sup>, including photon dose, using both the standard (i.e., Hp(0.07)) epidermis thickness of 70 µm, as well as an epidermis thickness of 400 µm. The 400 µm value was selected as a conservative average (male and female) representation of the epidermis layer for the palm side of the hand (also applicable to the sole of the foot), based on guidance in ICRP 89 (page 197) [9]. Due to Varskin 5.3's exclusion of skin doses due to alpha radiation, radionuclides with alphas emissions above 7 MeV (Pb-212, Ra-223, Ra-224, Ra-226, Ac-225) were revisited and skin doses calculated using Varkin+ 1.2 [7], using the same input parameters listed above. Details about alpha contamination and the comparison of the dose evaluation between the codes are provided in [8].

### Internal dose

This section includes the ICRP internal dose coefficients for workers, which may be used to estimate internal dose from inhalation and ingestion of the radionuclide of interest. These dose coefficients were obtained from ICRP Publications 130, 134, 137, 141 and 151 [11], using the ICRP's OIR 2022 Data Viewer tool (available for download from the ICRP website). In the case of inhalation, the coefficients listed are for a particle size (activity aerodynamic diameter, AMAD) of 5 µm. Many radionuclides have different inhalation dose coefficients for different solubility types which depend on the chemical compound. This booklet includes the most conservative inhalation dose coefficients. We encourage users that are aware of the solubility type and/or chemical compound of the nuclides in their work environments to download and use the ICRP's OIR 2022 Data Viewer tool so that the most appropriate dose coefficient may be applied.

## Part 4 – Clearance and exemption

This section summarizes CNSC exemption quantities in becquerel per gram (Bq/g) and Bq, unconditional clearance levels in Bq/g, and nuclide classification. The values published under "release of surface contaminated objects" are based on the values found in table 1 of the American National Standards Institute (ANSI) standard N13.12-2013 [12]. When the radionuclide of interest is present in table 1 of the ANSI standard, the value is given as published in the standard. When the radionuclide is not present, the method described in annex A of the ANSI standard was used to ascertain the group (1, 2, 3, 4 or 5) to which the radionuclide of interest should be attributed, and the corresponding surface contamination value was assigned. This value includes both fixed and removable contamination and applies to the free release (e.g., municipal landfill, recycling) of surface contaminated items or objects, as opposed to the contamination criteria associated with the nuclide class (A, B, C) which relates to the decommissioning of rooms within a licensed facility. Since the surface contamination criteria in ANSI N13.12-2013 are calculated based on exposure scenarios that would yield a "worst case" annual dose to an individual of 10 microsieverts (µSv), these values are suitable for use as conditional clearance levels, as defined in the *Nuclear Substances and Radiation Devices Regulations*.

---

## Part 5 – Detection and measurement

### Method of detection

There are two categories under this section: contamination and dose rate. Detector types that are commonly found in instruments used for contamination or dose rate measurement, capable of detecting the radiations emitted by the radionuclide of interest, are included in each category as applicable. When numbers are included under each category, the detector types ranked higher (#1 vs. #2), will yield a distinctly higher measurement efficiency as compared to the detector types ranked lower. The inclusion of a particular detector type on the information sheet does not necessarily guarantee that the instrument will be suited to meet any given regulatory detection criterion or be able to accurately measure a dose rate to within +/- 20% of the true radiation dose. For example, a halogen quenched thin window *Geiger-Mueller* (GM) contamination meter will only yield a counting efficiency of 0.4% to 0.8% when measuring Tc-99m; however, because Tc-99m is detectable using this type of device, it is included on this nuclide's information sheet. Similarly, an energy compensated GM dose rate meter may only yield a dose response of 5% to 10% (i.e., 90% to 95% below the true dose) when exposed to Cd-109, but again, because Cd-109 is detectable using this type of device, it is included on this nuclide's information sheet. Manufacturers' specifications should always be considered when taking measurements. Minimum counting times should be established by the users based on minimum detectable activity calculations, which should be set below the regulatory criterion, using published or experimentally verified efficiencies and documented conditions for use. The list of detector types found in the *Radionuclide Information Booklet* may not encompass all detector technologies currently available.

### Dosimetry

Dosimetry techniques that could be used to measure radiation doses from the radionuclide of interest are indicated in this section.

## Part 6 – Safety precautions

This section refers to the emergency procedures in appendix B and the general safety precautions in appendix C that should be applied if necessary.

### Uranium (processed, natural isotopic distribution)

The last information page is different than the rest. It deals with processed uranium containing natural isotopic distributions. In other words, U-238, U-235 and U-234 after it has been mined and chemically separated from its progeny, and after the short-lived progeny (Th-234, Pa-234m, and Th-231) have grown back in, without any enrichment. The isotopic ratios (by activity) were computed using published representative isotopic compositions (by mass) [13], along with the specific activities for U-238/235/234 defined in Nucleonica's Datasheets application [1]. The following table summarizes these results:

	Representative isotopic composition (% per g)	Specific activity (Bq/g)	Activity (Bq) in 1 g	% per Bq
U-238	99.27450%	1.2436E+04	1.23E+04	48.28%
U-235	0.72000%	7.9960E+04	5.76E+02	2.25%
U-234	0.00550%	2.3000E+08	1.27E+04	49.47%

The isotopic distributions by activity (i.e., % per Bq) above were used in the uranium information page. When a Bq is quoted on the page, it refers to a Bq of total uranium, in other words, 0.4828 Bq of U-238, Th-234, and Pa-234m, 0.0225 Bq of U-235 and Th-231, and finally, 0.4947 Bq of U-234. These same isotopic distributions were applied to the emissions table. For example, U-235 has a gamma emission at 185.71 keV, with a 57.1% probability. In the emissions table on the uranium information page, this gamma line is assigned a 1.29% probability (57.1% x 0.0225).

For the internal dose coefficients, while the other nuclide information pages only provide the most conservative coefficient for both inhalation and ingestion, because of the importance of uranium, all coefficients are given for

---

every chemical type, as described in ICRP Publications 130, 134, 137, 141 and 151 [9], using the ICRP's OIR 2022 Data Viewer tool. The internal dose coefficients for processed uranium were calculated by applying a weighted average using each uranium isotope's (U-238, U-235, U-234) published coefficient and the isotopic distributions (by activity) described above. The internal dose coefficients on the uranium information page may not be consistent with those in REGDOC-2.7.2; however, they can be used as default values when no site-specific data are available. The internal dose coefficients on the uranium information may not necessarily apply to some uranium compounds that do not fall neatly into the default Type F, M, S F/M or M/S categories, or for uranium compounds for which the shorter-lived progeny have not yet grown back in (e.g., fresh yellowcake).

For the clearance levels, since all 3 uranium isotopes of interest have identical exemption quantities, unconditional clearance levels, nuclide classes and ANSI N13.12-2013 clearance values, there was no need to perform any isotope distribution averaging.

## H-3

### Part 1 – RADIONUCLIDE IDENTIFICATION

Chemical symbol: H      Common name: Tritium      Atomic weight: 3      Atomic number: 1

### Part 2 – RADIATION CHARACTERISTICS

Physical half-life: 12.33 years

Decay scheme: H-3 (12.33 y,  $\beta^-$  100%)  $\rightarrow$  He-3 (stable)

Radiation type	Most abundant emissions (>10 keV, >0.01%)	Most energetic emissions (>10 keV, >0.01%)	Shielding information (mm)

Alpha	None	None	Not applicable

### Part 3 – DOSE RATE CONSTANTS AND COEFFICIENTS

#### External dose

Tritium is not an external radiation hazard.

#### Internal dose

	Ingestion	Inhalation	
Compound type	Unspecified compounds	Tritiated water	Elemental tritium gas
Worker dose coefficient	1.9E-11 Sv/Bq	2.0E-11 Sv/Bq	2.0E-15 Sv/Bq

### Part 4 – CLEARANCE AND EXEMPTION

<b>CNSC exemption quantity:</b>	1 MBq/g or 1 GBq	<b>CNSC classification:</b>	Class C
<b>CNSC unconditional clearance level:</b>	100 Bq/g	<b>Release of surface contaminated objects:</b>	100 Bq/cm <sup>2</sup> (fixed + removable)

### Part 5 – DETECTION AND MEASUREMENT

#### Method of detection (gamma dose rate):

Not applicable

#### Method of detection (contamination):

- Hand-held: windowless gas-flow proportional
- Non-portable: liquid scintillation counter

#### Dosimetry

External: Not applicable

Internal: In-vitro (urinalysis)

### Part 6 – SAFETY PRECAUTIONS

For emergency procedures, please refer to appendix B.

For general safety precautions, please refer to appendix C and apply if necessary.

Note: Tritium is an internal hazard only and cannot generally be detected with handheld equipment. Tritium can also migrate through conventional latex/nitrile gloves and plastic bottles. Tritium can be absorbed through the skin.

## Appendix A: Concrete TVL validation

Published HVL and TVL concrete values can vary considerably. For example, an often quoted TVL for concrete for Tc-99m is 6.6 cm, while the value found in the *Radionuclide Information Booklet* is 15.1 cm. These variations are primarily due to broad beam versus narrow beam calculations. Narrow beam calculations are not representative of an isotropic source (such as an injected patient) and do not factor in build-up in the shielding material. In order to validate the concrete HVL and TVL values, a comparison between various means of calculation was performed. The first and second concrete TVL values for Co-60, Cs-137, F-18, and Tc-99m were also computed using the Monte Carlo N-Particle transport code (MCNP6) for comparison with the values obtained using Nucleonica. The MCNP6 simulation comprised a series of concentric 5 cm thick concrete spheres, with air and a detector placed between each sphere. All TVL values computed using MCNP6 and Nucleonica were within approximately  $\pm 10\%$  of each other. A third comparison was also made using RadPro Calculator [14] (using build-up), a free online tool. The first and second TVL values computed using RadPro were very similar to the Nucleonica values. Note that ordinary NIST concrete with a density of  $2.3 \text{ g/cm}^3$  was used for all three methods of computation.

Nucleonica results were used throughout the *Radionuclide Information Booklet* because the Nucleonica nuclide library is complete (as opposed to RadPro's available list of nuclides), and MCNP6 simulations are somewhat labour intensive. Below is a table comparing all the results:

CONCRETE TVL (cm)	MCNP6	Nucleonica	Rad Pro Calculator
Co-60 TVL 1	32	30.5	28
Co-60 TVL 2	19.5	21.1	23.6
Cs-137 TVL 1	26	25.5	23.8
Cs-137 TVL 2	17	16.0	16.3
F-18 TVL 1	24	24	21.7
F-18 TVL 2	15.5	14.4	14.7
Tc-99m TVL 1	14.5	15.1	13.3
Tc-99m TVL 2	9.5	8.3	8.7

## **Appendix B: Emergency procedures**

In the case of an emergency, the radiation safety officer should be contacted as soon as practicable. The following actions, including cleanup, should be carried out by qualified individuals. In cases where life threatening injury has resulted, treat the injury first and deal with personal decontamination second.

### **Personal decontamination techniques**

- Wash well with soap and tepid water and monitor skin (see [CNSC Expectations for Licensee Response During \(nuclearsafety.gc.ca\)](https://www.nuclearsafety.gc.ca/eng/expectations_for_licensees/response_during_emergency.asp))
- Do not abrade skin, only blot dry
- Decontamination of clothing and surfaces are covered under operating and emergency procedures

### **Spill and leak control**

- Alert everyone in the area
- Clear area
- Summon aid

### **Emergency protective equipment**

- Gloves
- Footwear covers
- Safety glasses
- Outer layer or easily removed protective clothing
- Suitable respirator (if the radionuclide is potentially volatile\*)

\* potentially volatile radionuclides will have an internal dose coefficient for both vapour and aerosol on the information sheet

**CNSC duty officer emergency telephone line: 613-995-0479 or 1-844-879-0805**

## Appendix C: General safety precautions

### Unsealed sources

- Wear appropriate personal protective equipment (PPE):
  - laboratory coat
  - coveralls
  - shoe covers
  - safety glasses or goggles
  - disposable gloves (two pairs may be worn as an extra precaution and changed often, especially in cases where materials are volatile and/or could be absorbed through the gloves)
  - suitable respiratory protection (if the radioactive material is in the form of dust or powder, or if it is potentially volatile)
- Non-disposable PPE should be monitored before leaving the laboratory
- Monitor hands and feet after removal of PPE
- Optimize time, distance, and shielding
  - Keep handling time to a minimum
  - Use tongs, syringe shields, plastic screens, and lead aprons where appropriate
- Use disposable absorbent liners on trays
- Gases and volatile liquids should be handled in ventilated enclosures
- Monitor equipment and supplies for loose contamination before removal from laboratory
- Extremity dosimeters should be worn if annual extremity doses may exceed 50 mSv

### Sealed sources

- Optimize time, distance, and shielding
  - Keep handling time to a minimum
  - Use tongs and shielding where appropriate
- Extremity dosimeters should be worn if annual extremity doses may exceed 50 mSv
